

DESIGN PATTERNS :-

- A design pattern in programming is a reusable solution to a common problem that occurs during software development or design.
- These patterns provide structured approach to solve design & development issues.
- used to create more maintainable, flexible & scalable code.

[1] Creational pattern :-

- These pattern focus on object create mechanism.
- Provide ways to create object in a manner that is flexible and maintainable.
- Based on application specific requirements we choose a object creation mechanism.

[2] Structural Pattern:-

- These patterns focus on class & objects to create large structures while keeping them flexible and efficient.

to ensure that classes and objects

[3] Behavioral Pattern :-

→ used for interaction & communication between object and classes.

→ Provide solution for efficiently manage flow of control, behaviour between object.

* Creational Pattern :-

i) Singleton Pattern :-

→ Ensures that only one instance of a class is created & provide global point of access to it.

→ used when we want to have single shared instance of class throughout the application.

Ways to create Singleton class :-

[1] Eager initialisation

[4] Double check

[2] Lazy initialisation

[5] Bill Pugh Solution

[3] Synchronized block.

[6] Enum

Main class :-

Public class main

{

Public static void main (String args[])

{

DBConnection obj = DBConnection.getInstance();

}

}

Eager Initialisation :-

```
Public class DBConnection
{
    private static DBConnection conObject = new DBConnection();

    private DBConnection() {}

    private static DBConnection getInstance()
    {
        return conObject;
    }
}
```

Lazy initialization:-

```
Public class DBConnection
{
    private static DBConnection conObject;

    private DBConnection() {}

    public static DBConnection getInstance()
    {
        if (conObject == null)
            conObject = new DBConnection();

        return conObject;
    }
}
```

Synchronization BLOCK :-

```
Public class DBConnection
{
    private static DBConnection conObject;

    private DBConnection() {}

    synchronized public static DBConnection getInstance()
    {
        if (conObject == null)
            conObject = new DBConnection();

        return conObject;
    }
}
```

Double check locking system:-

```
Public class DB Connection
{
    Private static volatile DB Connection con = new DB Connection
    Private DB Connection () {}

    Public static DB Connection get Instance ()
    {
        Synchronize d (DB Connection . class)
        {
            if (con == null)
            {
                con = new DB Connection ();
            }
        }
        return con;
    }
}
```

Big Push Singleton:- (uses eager initialisation)

```
Public class DBC
{
    Private DBC () {}

    Private static class DB Helper
    {
        Private static final DB = INSTANCE_OBJECT = new DBC
    }

    Public static DB get Instance ()
    {
        return DB Helper . INSTANCE_OBJECT
    }
}
```

ENUM:-

```
Public enum DBC
{
    INSTANCE

    Public static do something () {
    }
}
```

Builder Pattern :-

→ Builder Pattern is a creational design pattern that allows you to construct complex objects step-by-step separating the construction logic from the representation.

→ Useful when objects have many optional fields

→ Avoid telescoping constructors.

Without Builder pattern

Person.java :-

```
Public class Person
{
    private String name;
    private int age;

    Public Person (String name, int age)
    {
        this.name = name;
        this.age = age;
    }

    Public void display ()
    {
        S.O.P ("Name" + name + "...");
    }
}
```

Test.java:

```
Public class Test
{
    Public static void main (String args[])
    {
        Person p = new Person ("Vikram", 35);
        p.display ();
    }
}
```

With builder pattern

Person.java.

```
Public class Person
{
    private String name;
    private int age;

    private Person (Builder builder)
    {
        this.name = builder.name;
        this.age = builder.age;
    }

    Public void display ()
    {
        S.O.S (name + "...");
    }

    Public static class Builder
    {
        private String name;
        private int age;

        Public Builder setName (String name)
        {
            this.name = name;
            return this;
        }

        Public Builder setAge (int age)
        {
            this.age = age;
            return this;
        }

        Public Person build ()
        {
            return new Person (this);
        }
    }
}
```

Inside main

```
Person p = new Person.Builder ()
    .setName ("Kohli")
    .setAge (35)
    .build ();
p.display ();
```

Factory Pattern :-

→ A creational design pattern that provides an interface to create objects in a superclass but allows subclass to alter the type of objects that will be created.

→ Avoid using new directly in the client

→ We will use factory pattern when we need to create object based on input or condition.

Code :-

```
Public interface shape {
```

```
    void draw();
```

```
}
```

```
Public class Circle implements shape {
```

```
    Public void draw () {
```

```
        system.out.println ("Drawing a circle");
```

```
    }
```

```
}
```

```
Public class Square implements shape {
```

```
    Public void draw () {
```

```
        system.out.println ("Drawing a square");
```

```
    }
```

```
}
```

```
Public class Shape Factory
```

```
{
```

```
    Public shape getShape (String type)
```

```
    {
```

```
        if (type.equalsIgnoreCase ("circle")) {
```

```
            return new Circle();
```

```
        } else if (type.equalsIgnoreCase ("square")) {
```

```
            return new Square();
```

```
        }
```

```
    }
```

```

Public class Main
{
    Public static void main (String[] args)
    {
        ShapeFactory factory = new ShapeFactory();
        Shape s1 = factory.getShape ("circle");
        s1.draw();
        Shape s2 = factory.getShape ("square");
        s2.draw();
    }
}

```

Structural Pattern :-

Adapter:

→ Adapter Pattern is a structural pattern that allows object with incompatible interfaces to work together by converting one interface into another.

→ Bridge the gap between two incompatible interfaces.

Client → Target (expected interface)

Adapter

Adaptee (incompatible class)

Code:

```

class OldPrinter {
    Public void printOld () {
        System.out.println ("old printer");
    }
}

```

```

interface PPrinter {
    void print();
}

class PPrinterAdapter implements PPrinter {
    private OldPrinter oldPrinter;

    public PPrinterAdapter (OldPrinter oldPrinter) {
        this.oldPrinter = oldPrinter;
    }

    public void print() {
        oldPrinter.print();
    }
}

public class Test {
    public static void main (String[] args) {
        OldPrinter old = new OldPrinter();
        PPrinter adapter = new PPrinterAdapter (old);
        adapter.print();
    }
}

```

[2] Composite Pattern :-

→ used to treat individual objects and groups of objects in a uniform way.

Contains List <Component>

```
public interface Employee {  
    void showDetails();  
}
```

```
public class Developer implements Employee {  
    private String name;  
  
    public Developer (String name) {  
        this.name = name;  
    }  
  
    public void showDetails() {  
        System.out.println ("Developer: " + name);  
    }  
}
```

```
public class Manager implements Employee {  
    private String name;  
    private List <Employee> team = new ArrayList <>();  
  
    public Manager (String name) {  
        this.name = name;  
    }  
  
    public void add (Employee emp) {  
        team.add (emp);  
    }  
  
    public void showDetails() {  
        System.out.println ("Manager: ", +name);  
        for (Employee e : team) {  
            e.showDetails();  
        }  
    }  
}
```

```
public class Test {  
  
    public static void main (String[] args) {  
        Developer dev1 = new Developer ("Rahul");  
        Developer dev2 = new Developer ("Kiran");  
    }  
}
```

```
manager manager = new Manager ("vijay");  
manager.add (dev1);  
manager.add (dev2);  
manager.show Details();  
}
```

Behav

Behavioral Pattern

Observer Pattern

→ where an object maintains a list of dependents and notified them automatically when its state changes.

```
public interface Observer {  
    void update (String message);  
}
```

```
public class Followee implements Observer {  
    private String name;  
    public Followee (String name) {  
        this.name = name;  
    }  
    public void update (String message) {  
        System.out.println (name);  
    }  
}
```

```
public interface Subject {  
    void addObserver (Observer o);  
    void removeObserver (Observer o);  
    void notifyObserver (String msg);  
}
```

```
import java.util.*;
```

```
public class Channel implements Subject {  
    private List<Observer> observers = new ArrayList<>();  
    public void addObserver (Observer o) {  
        observers.add (o);  
    }  
}
```

```
Public class Test {
```

```
    Public Static void main (String[] args) {
```

```
        channel chanel = new channel();
```

```
        Follower f1 = new Follower ("viva");
```

```
        channel.addObsexxvex (f1);
```

```
        channel.upload ("++highlights");
```

```
    }  
}
```
